NEXT**  
EXHIBITION · TRAINING · NETWORKING

# Global lithium-ion battery cell demand (GWh)

Driven by electrification of transport and energy storage

## 2022 Projection

Source: HIS; WEF; McKinsey Battery Demand Model 2022

## 2023 Projection

Source: McKinsey 2023 - Battery 2030: Resilient, sustainable, and circular

# Anatomy of a lithium-ion battery

The most basic electrochemical unit

# Battery chemistry – A spectrum of options

Most elements can be used for a form of energy storage

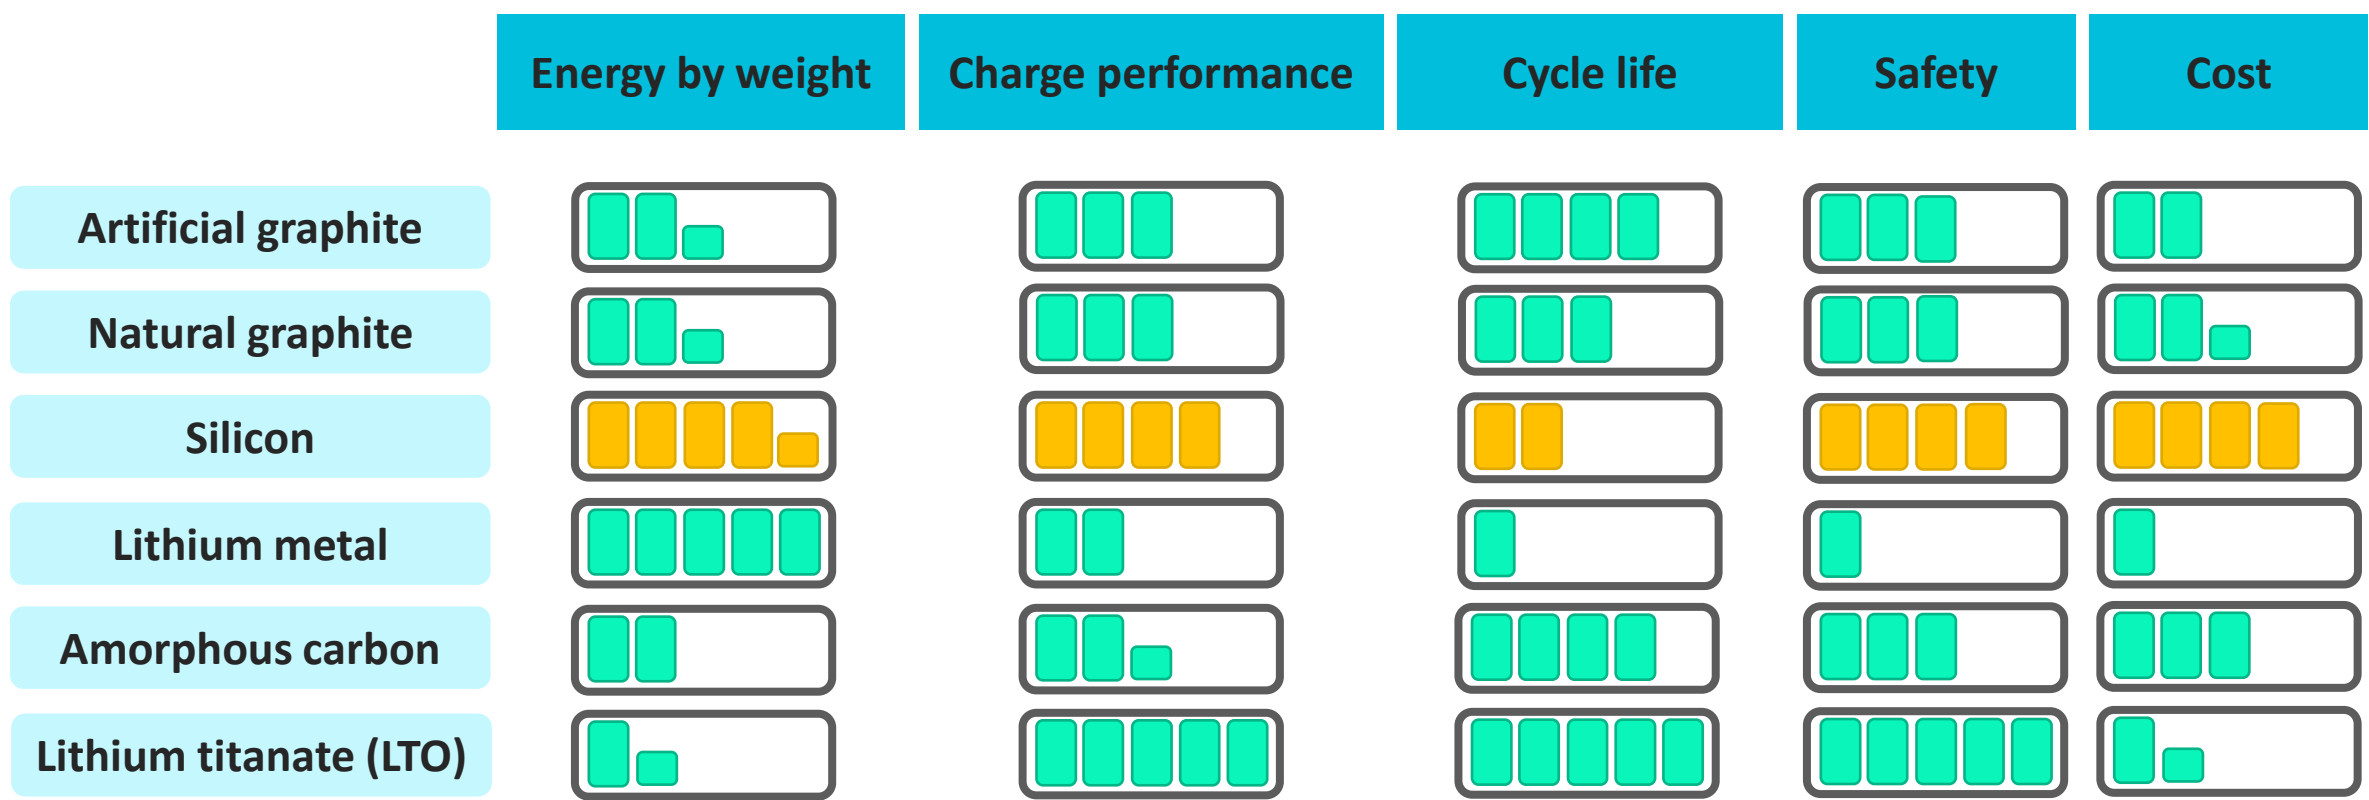

Source: Nitta et al., Materials Today Volume 18, Number 5 June 2015

# The anode (-)

Different anode materials can have very different characteristics across several metrics

Silicon and lithium metal's cycle life can be enhanced by use of appropriate enabling technologies

# Why silicon?

Silicon stores close to 10x more  $\text{Li}^+$  by weight and 3x more  $\text{Li}^+$  by volume

Near term opportunity to develop cheaper, smaller and lighter batteries

VS

$^{12}\text{C}$  - Graphite

371 mAh/g

$^{28}\text{Si}$  - Silicon

3,579 mAh/g

# CLEAN ENERGY TECHNOLGY DIVISION

‘Enabling technology for  
smaller, lighter and  
cheaper batteries’

SILICON

# AnteoTech – High silicon anode

Combining know how and complementary technologies to provide a step change in battery performance

**500+ charge / discharge cycles**

demonstrated whilst retaining 90% of the initial capacity in high silicon anode

**Low grade, unrefined silicon**

competitors use super refined silicon - expensive, limited and carbon intensive

**8.5x cheaper**

active material on a \$/kWh basis

**35% improvement**

in energy capacity

**3x thinner**

and also lighter

**Silicon anodes can make batteries smaller, lighter and cheaper**

# The cathode (+)

- Complex metal oxides
  - **1979:** R&D on lithium-ion batteries commences using LCO
  - **1991:** First LIB is commercialized by Sony (Coke/LCO)
  - **1996:** Lithium manganese oxide (LMO) is commercialized
  - **1996:** Lithium iron phosphate (LFP) is discovered
  - **1999:** Lithium nickel cobalt aluminium oxide (NCA) is discovered
  - **2000:** Nickel manganese cobalt chemistries (NMC) appear
- Further development of chemistry categories
  - **Higher Nickel** content in NMC to drive up capacity
  - **Higher Manganese** content in NMC to drive higher voltages
  - **LMFP:** Manganese introduction into LFP to drive to higher voltages
- Possible future cathode chemistries
  - **Sulfur** and possibly Air ( $O_2$ )

# The NCM family of materials

## Early NCM variants (past)

NCM 111 - Discharge capacity: ~ 150 mAh/g  
 NCM 523 - Discharge capacity: ~ 165 mAh/g

## Nickel rich variants (now)

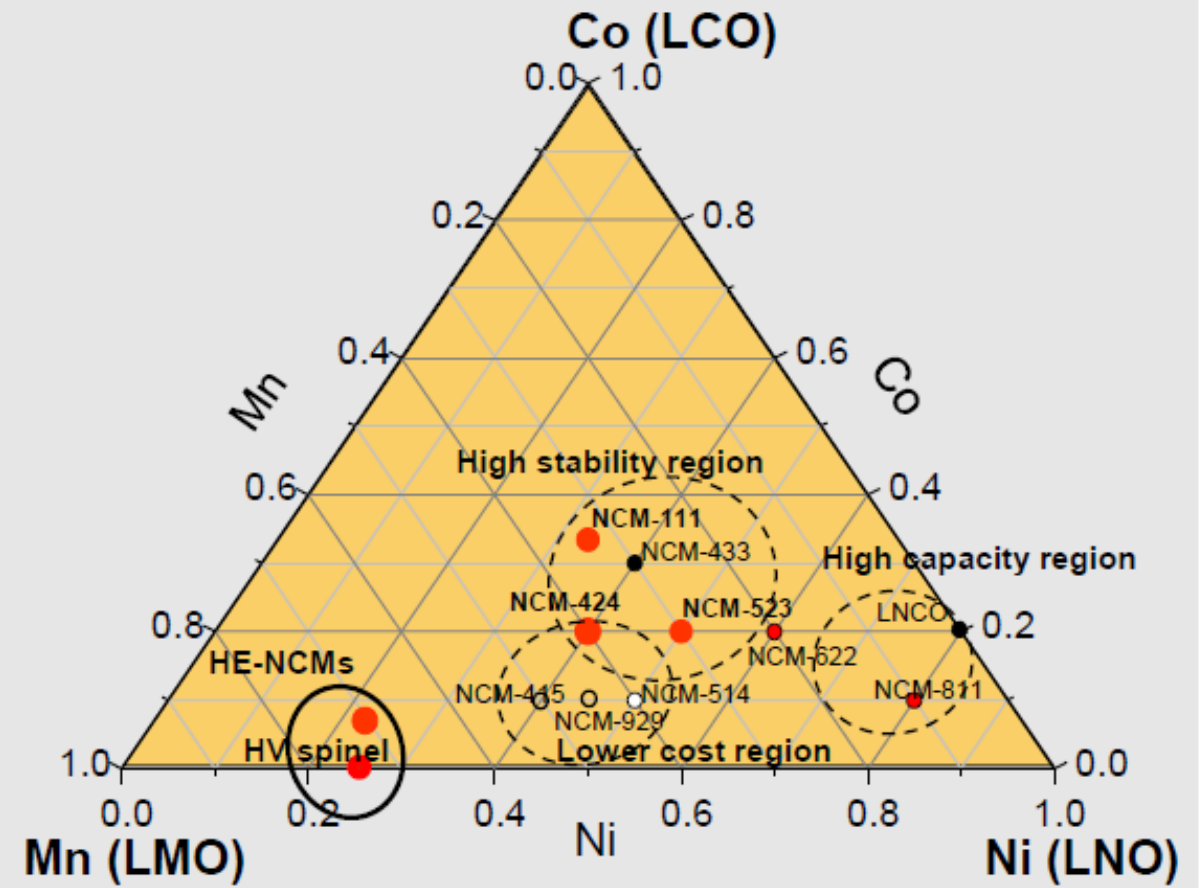

NCM 622 - Discharge capacity: ~ 175 mAh/g  
 NCM 811 - Discharge capacity: ~ 200 mAh/g

## Manganese rich variants (future)

HE-NCM - Discharge capacity: > 250 mAh/g  
 HV-Spinel - Discharge capacity: ~ 140 mAh/g

$$Wh = Ah \cdot V \text{ vs. } Ah \cdot V$$

NCM COMPOSITION DIAGRAM

## Beyond lithium-ion

# Solid-state batteries

- Conventional lithium-ion battery electrolytes consist of a mixture of flammable and toxic solvents
  - Electrolyte fills pores in anode, cathode and separator
  - Transports lithium ions between the two electrodes
- Solid-state electrolyte systems

## Polymers

PEO + additives

- + Easy to scale & cost-effective processing
- + Good interfacial compatibility
- + Highly flexible

- High operating temperatures required
- Lowest ionic conductivity
- Limited energy density improvement

## Oxides

Perovskite, NASICON, Garnet

- + Good ionic conductivity
- + High strength but brittle
- + Good safety (thermal stability)

- Poor interfacial compatibility (resistance)
- Difficult to scale for mass manufacturing
- High sintering temperatures required

## Sulphides

Sulphide glasses & ceramics, Agryodite

- + Highest ionic conductivity
- + Good interfacial compatibility
- + Reasonably scalable

- High reactivity with water and air
- High cell pressure required for performance
- Can generate toxic byproducts ( $H_2S$ )

# Solid-state electrolytes and batteries

	Claim	Practical consideration
<b>Safety</b>	<ul style="list-style-type: none"> <li>No flammable electrolyte leads to better safety and thermal stability</li> </ul>	<ul style="list-style-type: none"> <li>Higher energy density paired with pure lithium metal as the anode does not necessarily mean better safety</li> </ul>
<b>Energy density</b>	<ul style="list-style-type: none"> <li>Solid state electrolytes enable higher energy densities</li> </ul>	<ul style="list-style-type: none"> <li>Without changing to a different anode and cathode chemistry gravimetric energy density would be reduced</li> </ul>
<b>Power capability (Charge)</b>	<ul style="list-style-type: none"> <li>Fast charging is advertised by some companies as a feature of solid-state batteries</li> </ul>	<ul style="list-style-type: none"> <li>Most solid-state chemistries struggle to deliver fast charge performance based on interface issues and lower ionic conductivities at room temperature</li> </ul>
<b>Manufacturing at scale</b>	<ul style="list-style-type: none"> <li>Fewer manufacturing steps lead to a reduction in cost</li> </ul>	<ul style="list-style-type: none"> <li>Processing steps are generally more complex and may require additional high temperature sintering steps and inert gas conditions paired with high capital investment</li> </ul>
<b>Battery cost</b>	<ul style="list-style-type: none"> <li>Simplified battery pack cooling (heating as opposed to cooling) and protection packaging</li> </ul>	<ul style="list-style-type: none"> <li>Battery pack heating requires re-engineering of end application while solid-state batteries generally require higher pressure to work well</li> </ul>

# Lithium - Metal oxide cathode

**${}^3\text{Li}$  - Lithium**

3,860 mAh/g

**Metal oxides (NCM)**

200+ mAh/g

# Lithium - Metal oxide cathode

Dendrite formation and controlled lithium deposition are key challenges

*External heating failure vs. Internal short-circuit vs. Nail penetration test*

Source: Kuehnle et al., Journal of the ECS, Vol 169, 2022

Source: Bates et al., Joule, Vol 6, 2022

# Lithium - Sulfur

${}^3\text{Li}$  - Lithium

3,860 mAh/g

${}^{16}\text{S}$  - Sulfur

1,675 mAh/g

# Lithium - Sulfur

## Targeted benefits

- High specific capacity: 1675 mAh/g (theoretic)
- Very light weight cells (promises cells with >400 Wh/kg)
- No heavy metals in cathode

## Challenges

- Complex working mechanism (polysulfide formation)
- Sulfur is an electrical insulator (requires carbon)
- Sulfur has low density (impacts Wh/L)
- Average cell voltage is 2.1V (1.7V lower compared to LIB)
- Low published energy density values (50% lower than LIB)
- Poor cycle life at full depth of discharge or high rate

## Lower predicted cost

- Sulfur costs < \$150/t\*
- Cobalt costs > \$33,000/t\*
- Nickel costs > \$20,500/t\*

**Anode:** Lithium metal foil

**Cathode:** Sulfur/carbon composite

**Electrolyte:** New formulations required

**Separator:** Can be standard materials

# Lithium - Sulfur

**Energy cell (2016)**  
 400 Wh/kg  
**310 Wh/L**

**Energy cell (2013)**  
 350 Wh/kg  
**320 Wh/L**

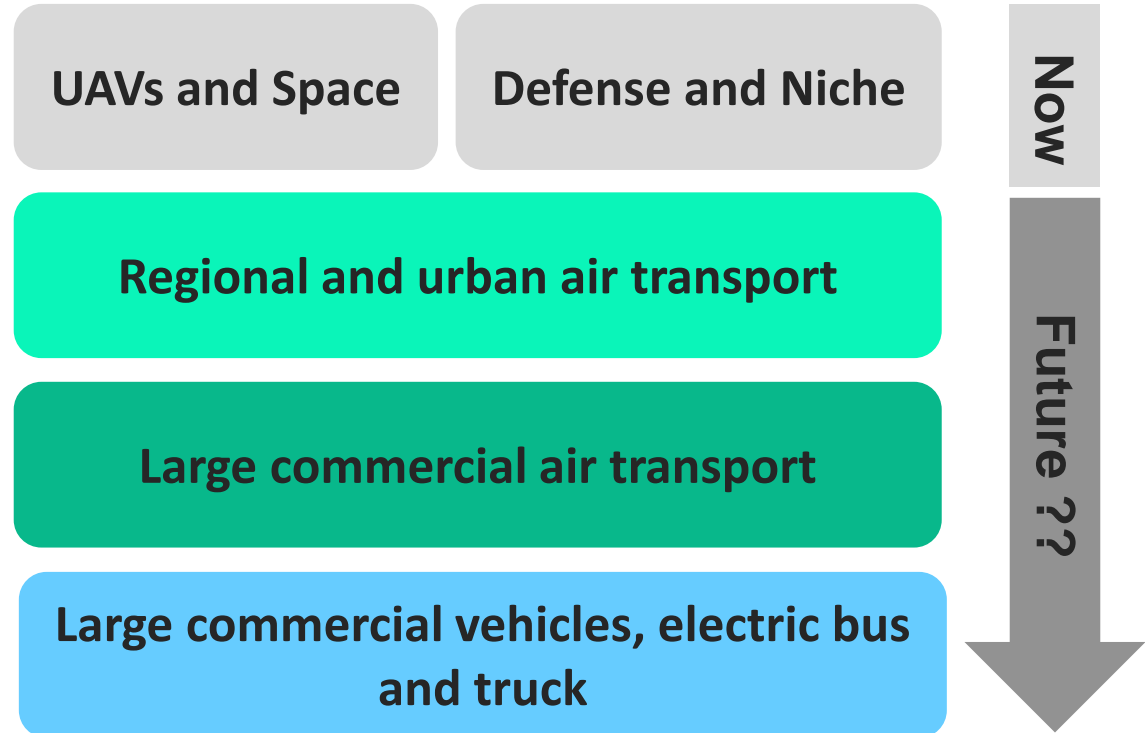

**Energy cell**  
 244 Wh/kg\*  
**650Wh/L\***

**Next generation**  
 Lithium-ion

**Advanced cells**  
 > 300 Wh/kg  
**> 750Wh/L**

- **Most promising applications**

- Low weight is key
- Space is available
- Cycle life is secondary
